

GPU Graphics Pipeline (Part II)

Computer Graphics Yu-Ting Wu

Outline

- GPU graphics pipeline
- OpenGL graphics pipeline 1.x
- OpenGL graphics pipeline 2.0
- OpenGL and shader implementation

(Part I)

(Part II)

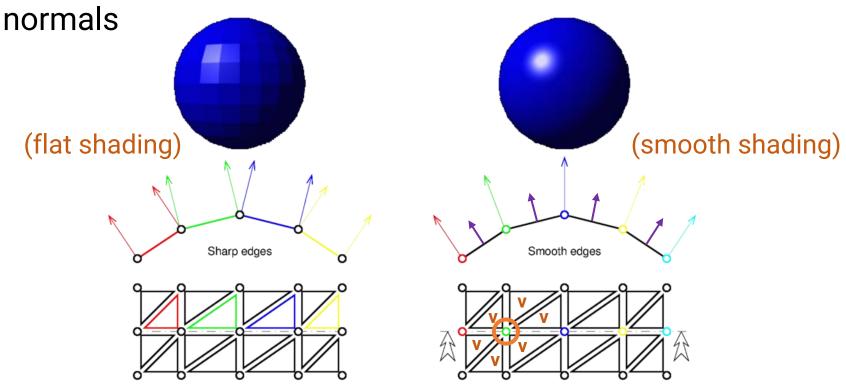

Outline

- GPU graphics pipeline
- OpenGL graphics pipeline 1.x
- OpenGL graphics pipeline 2.0
- OpenGL and shader implementation

Recap: Vertex Normal

 Compute by averaging the surface normals of the faces that contain that vertex

Can achieve much smooth shading than using triangle

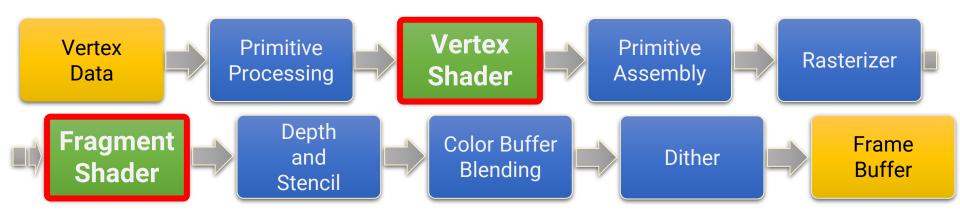

Recap: OpenGL (1.x) Fixed Function Pipeline

- All the functions performed by OpenGL are fixed and could not be modified except through the manipulation of the rendering states
- The stages shown in green have been replaced by shaders

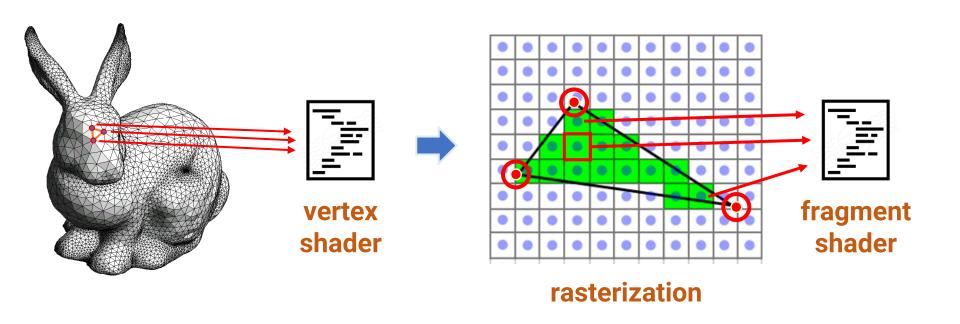

OpenGL (2.0) Graphics Pipeline

- Released in 2004
- Provide the ability to programmatically define the vertex transformation and lighting and the fragment operations (with small GPU programs called shaders)

Vertex Shader and Fragment Shader

- Important concepts
 - The vertex shader runs per vertex
 - The fragment shader runs per (rasterized) fragment

Vertex Shader (Run per Vertex)

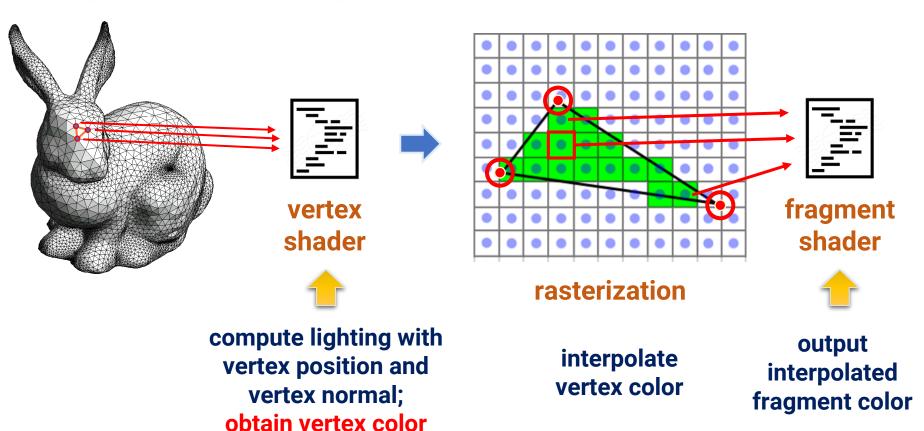

- Provide the programmers more flexibility regarding
 - How the vertices are transformed
 - We can also choose not to transform the vertices at all
 - How the lighting is computed
 - We can also choose to compute lighting in the fragment shader (per-fragment lighting)
- However, with great power, comes great responsibility
 - Programmers have to implement the functions provided by the fixed pipeline on their own
 - The primary responsibility of the vertex shader program is to transform the vertex position into Clip Space
 - Commonly, this is done by multiplying the vertex with the model-view-projection matrix

Fragment Shader (Run per Fragment)

- Replace the texture blending, color sum, fog, and alpha test operations from the fixed function pipeline
- Graphics programmers have to write a fragment program to perform these operations (of course, you can omit them if you do not care!)
- The primary responsibility of the fragment program is to determine the final color of the fragment
- Allow for different lighting and fog models, as well as an arbitrary combination of lighting and texture
- Allow for techniques such as per-pixel lighting, bump, normal mapping, etc.

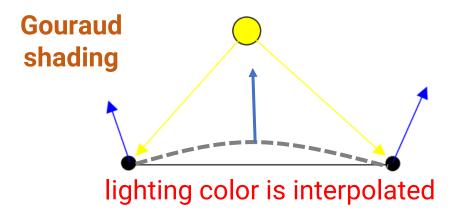

Per-Vertex Shading

 OpenGL 2.0 can still implement per-vertex shading (Gouraud shading)

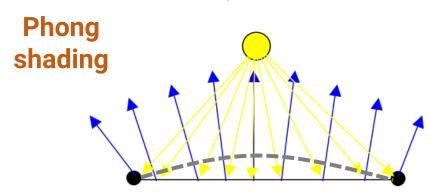

Per-Fragment Shading

Problem with Gouraud shading

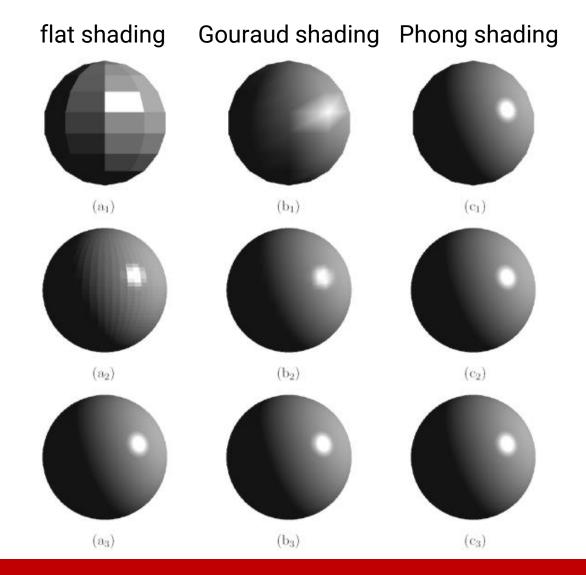

Phong shading (instead of Gouraud shading)

surface normal is interpolated (how? Rasterization!)

Per-Fragment Shading (cont.)

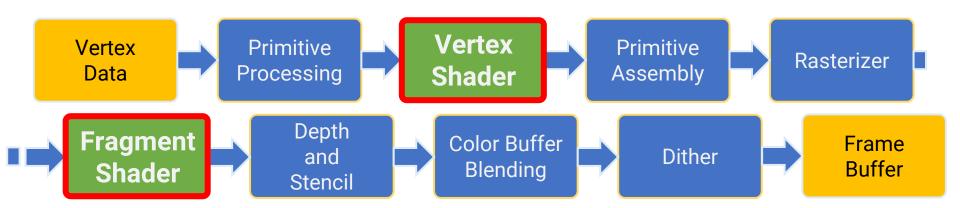

Outline

- GPU graphics pipeline
- OpenGL graphics pipeline 1.x
- OpenGL graphics pipeline 2.0
- OpenGL and shader implementation

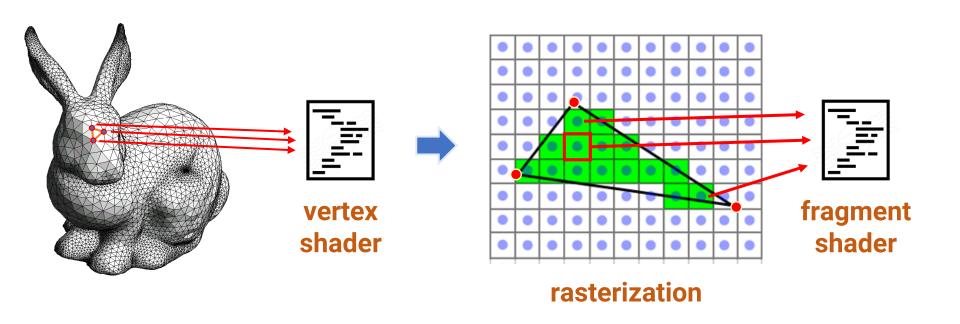

Recap: OpenGL 2.0 Graphics Pipeline

- Programmers need to provide the two shader programs
- Other stages maintain the same (set OpenGL states)

Recap: Vertex Shader and Fragment Shader

- Important concepts
 - The vertex shader runs per vertex
 - The fragment shader runs per (rasterized) fragment

Sample Project

You can find the sample code in the project, Shader

Prepare Shaders

- Shaders are just text files written in a special shader language, such as
 - OpenGL Shading Language (GLSL)
 - High-Level Shading Language (HLSL) for DirectX
 - Nvidia Cg (used by Unity)

the file extension does not matter!

```

                                                                Create, compile the fragment shader
                                                                and attach it to the shader program
   GLuint fsId = AddShader(shaderProgId, fs, GL_FRAGMENT_SHADE
```

Load and Create an OpenGL Shader (cont.)

```
// Link and compile shader programs.
GLint success = 0;
                                               Link all attached shaders to the program
GLchar errorLog[MAX_BUFFER_SIZE] = { 0_};
glLinkProgram(shaderProgId);
glGetProgramiv(shaderProgId, GL_LINK_STATUS, &success);
if (success = 0) {
    glGetProgramInfoLog(shaderProgId, sizeof(errorLog), NULL, errorLog);
    std::cerr << "[ERROR] Failed to link shader program: " << errorLog << std::endl;
    exit(1);
// Now the program already has all stage information, we can delete the shaders now.
qlDeleteShader(vsId);
                         Delete (free memory) vertex/fragment shader object
glDeleteShader(fsId);
// Validate program.
                                    Validate your shader program
glValidateProgram(shaderProgId);
glGetProgramiv(shaderProgId, GL_VALIDATE_STATUS, &success);
if (!success) {
    qlGetProgramInfoLog(shaderProgId, sizeof(errorLog), NULL, errorLog);
    std::cerr << "[ERROR] Invalid shader program: " << errorLog << std::endl;
    exit(1);
  // Get the location of uniform variables.
  // Discuss later
```

Vertex Shader

#version 330 core

Vertex attribute

glEnableVertexAttribArray(0)

layout (location = 0) in vec3 Position;

uniform mat4 modelMatrix; uniform mat4 viewMatrix; uniform mat4 projMatrix;

uniform variables communicated with the CPU

- Get location by glGetUniformLocation
- Set value by glUniformXXX

the main program executed per vertex

Vertex Shader

```
#version 330 core
```

Input: vertex attribute

glEnableVertexAttribArray(0)

```
layout (location = 0) in vec3 Position;
```

uniform mat4 MVP;

uniform variables communicated with the CPU

- Get location by **glGetUniformLocation**
- Set value by glUniformXXX

the main program executed per vertex

```
void main() {
    gl_Position = MVP * vec4(Position, 1.0);
    a built-in variable for the Clip Space coordinate
```

Fragment Shader

```
#version 330 core
```

uniform vec3 fillColor;

uniform variables communicated with the CPU

- Get location by glGetUniformLocation
- Set value by glUniformXXX

```
out vec4 FragColor;
```

Output: fragment data

the main program executed per fragment

```
void main() {
    FragColor = vec4(fillColor, 1.0);
}
```

Connect the Program with Shaders

Get the location of uniform variables in the shader

```
// Get the location of uniform variables.
locM = glGetUniformLocation(shaderProgId, "modelMatrix");
locV = glGetUniformLocation(shaderProgId, "viewMatrix");
locP = glGetUniformLocation(shaderProgId, "projMatrix");
locMVP = glGetUniformLocation(shaderProgId, "MVP");
locFillColor = glGetUniformLocation(shaderProgId, "fillColor");
```

Assign values to the uniform variables in shaders

```
// Bind shader and set parameters.
glUseProgram(shaderProgId); bind (there might be several shaders in your program)
glUniformMatrix4fv(locM, 1, GL_FALSE, glm::value_ptr(M));
glUniformMatrix4fv(locV, 1, GL_FALSE, glm::value_ptr(camera->GetViewMatrix()));
glUniformMatrix4fv(locP, 1, GL_FALSE, glm::value_ptr(camera->GetProjMatrix()));
// glUniformMatrix4fv(locMVP, 1, GL_FALSE, glm::value_ptr(MVP));
glUniform3fv(locFillColor, 1, glm::value_ptr(fillColor));

// Render the mesh.
if (mesh ≠ nullptr)
    mesh->Draw();

// Unbind shader.
glUseProgram(0); unbind
```

Bind and unbind to a shader program

the shader program you created void glUseProgram(GLuint program);

```
glUseProgram(shaderProgId);
// set parameters
// render something
glUseProgram(0);
```

 Get the location of uniform variables in the shader GLint glGetUniformLocation(

```
GLuint program, the shader program you created const GLchar *name
```

the uniform variable in the shader

```
// Get the location of uniform variables.
locM = glGetUniformLocation(shaderProgId, "modelMatrix");
locV = glGetUniformLocation(shaderProgId, "viewMatrix");
locP = glGetUniformLocation(shaderProgId, "projMatrix");
locMVP = glGetUniformLocation(shaderProgId, "MVP");
locFillColor = glGetUniformLocation(shaderProgId, "fillColor");
```

- Assign values to the uniform variables
- Lots of variants depending on the variable type, please refer to https://registry.khronos.org/OpenGL-Refpages/gl4/html/glUniform.xhtml

Assign values to the uniform variables

```
void glUniformMatrix4fv(

GLint location ,

GLsizei count ,

GLboolean transpose ,

const GLfloat *value

should the matrix be accessed in a transpose way

(since both OpenGL and GLM use column-major, we set it to FALSE)

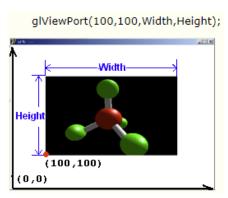

);
```

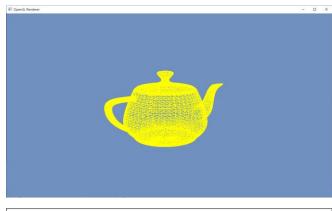

```
glUniformMatrix4fv(locM, 1, GL_FALSE, glm::value_ptr(M));
glUniformMatrix4fv(locV, 1, GL_FALSE, glm::value_ptr(camera->GetViewMatrix()));
glUniformMatrix4fv(locP, 1, GL_FALSE, glm::value_ptr(camera->GetProjMatrix()));
```

Resize Window

```
glutReshapeFunc(ReshapeCB);

Evoid ReshapeCB(int w, int h)
{
    // Update viewport.
    screenWidth = w;
    screenHeight = h;
    glViewport(0, 0, screenWidth, screenHeight);
    // Adjust camera and projection.
    float aspectRatio = (float)screenWidth / (float)screenHeight;
    camera->UpdateProjection(fovy, aspectRatio, zNear, zFar);
    MVP = camera->GetProjMatrix() * camera->GetViewMatrix() * M;
}
remember to reset the range of rendering in an
OpenGL window
```

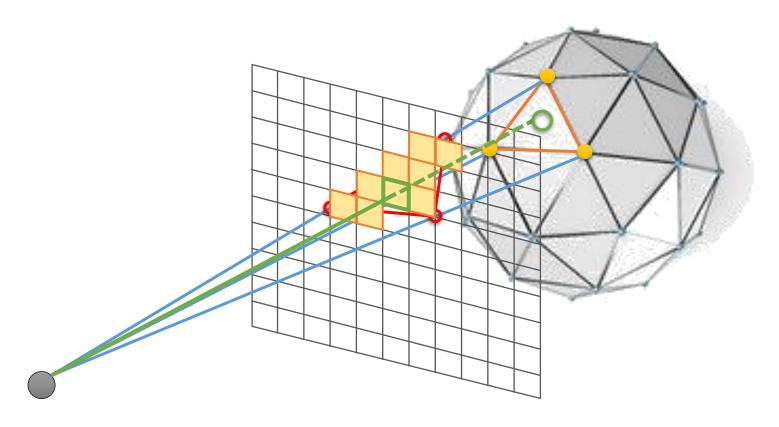

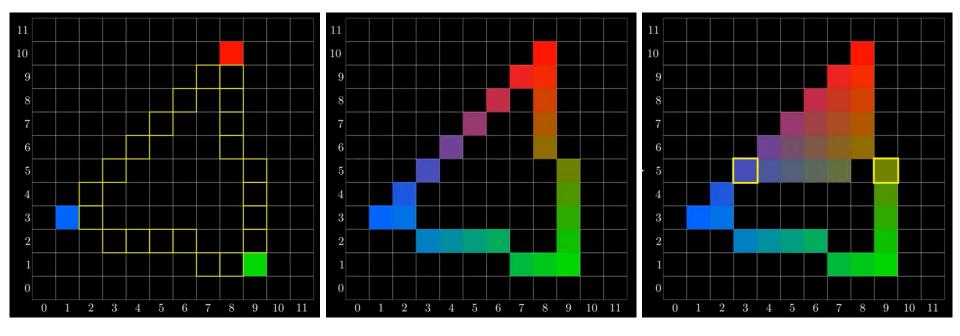

Vertex Attribute Interpolation

- Generate fragments for each triangle
- Interpolate vertex attributes at each fragment

Interpolate vertex color

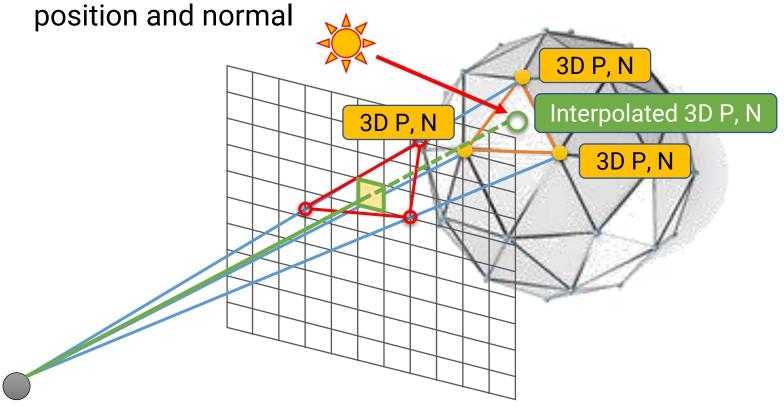

Attributes interpolation of edge pixels using vertices

Attributes interpolation of inner pixels using edge points

Interpolate geometry attributes

Compute lighting at each fragment (in the fragment shader)
requires per-fragment geometry attributes such as 3D

Example: interpolate world-space vertex position and world-space vertex normal

Vertex Shader

```
#version 330 core
 layout (location = 0) in vec3 Position;
 layout (location = 1) in vec3 Normal;
 // Transformation matrix.
 uniform mat4 worldMatrix;
 uniform mat4 normalMatrix;
                                  Tell OpenGL you
 uniform mat4 MVP;
                                   want to
 // Data pass to fragment shader.
                                  interpolate these
 out vec3 iPosWorld;
 out vec3 iNormalWorld;
                                   attributes
□void main()
     gl_Position = MVP * vec4(Position, 1.0);
     // Pass vertex attributes.
     vec4 positionTmp = worldMatrix * vec4(Position, 1.0);
     iPosWorld = positionTmp.xyz / positionTmp.w;
     iNormalWorld = (<u>normalMatrix</u> * <u>vec4(Normal, 0.0)</u>).xyz;
```

Fragment Shader

```
#version 330 core

// Data from vertex shader.
in vec3 iPosWorld;
in vec3 iNormalWorld;

out vec4 FragColor;

void main()
{
    vec3 N = normalize(iNormalWorld);
    FragColor = vec4(N, 1.0);
}
```

Ensure the interpolated normal has a unit length

world matrix for transforming normal (intro. in next lecture)

 Note: when you do this, you need to pass in the vertex normal attribute

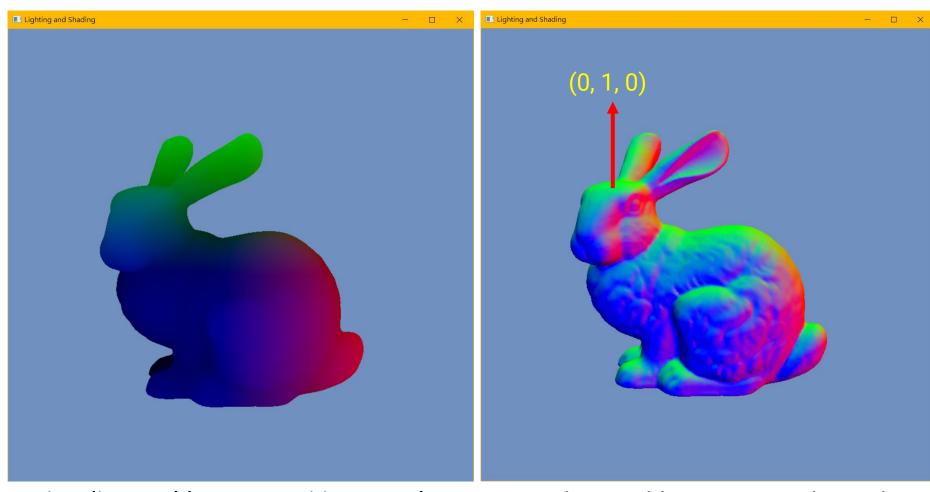

```
glEnableVertexAttribArray(0); the first attribute: in this case, position
glEnableVertexAttribArray(1); the second attribute: in this case, normal

glBindBuffer(GL_ARRAY_BUFFER, vboId);
glVertexAttribPointer(0, 3, GL_FLOAT, GL_FALSE, sizeof(VertexPN), 0);
glVertexAttribPointer(1, 3, GL_FLOAT, GL_FALSE, sizeof(VertexPN), (const GLvoid*)12);

// ... draw primitives

glDisableVertexAttribArray(0);
glDisableVertexAttribArray(1);
```

visualize world-space position as color

visualize world-space normal as color

- Remember the homogeneous coordinate for a 3D point (x, y, z) is (x, y, z, 1)
 - Why? To enable the combination of a translation matrix with other transformation matrices

$$\begin{bmatrix} x' \\ y' \\ z' \\ w \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & t_x \\ 0 & 1 & 0 & t_y \\ 0 & 0 & 1 & t_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} \qquad \begin{aligned} x' &= x + t_x \\ y' &= y + t_y \\ z' &= z + t_z \end{aligned}$$

- When transforming a vector, we represent a 3D direction (dx, dy, dz) by (dx, dy, dz, 0) because we do not want a translation for "direction"
 - Otherwise, the direction (0.578, 0.578, 0.578) will become (3.578, 4.578, 5.578) after a translation of (3, 4, 5)

CPU v.s. GPU

CPU (what we do in HW1)

loop through all vertices

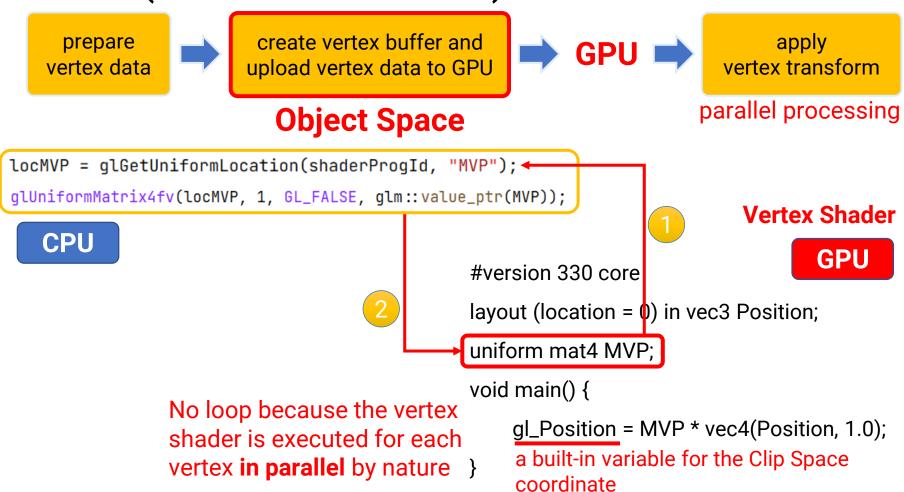

NDC

```
Ivoid ApplyTransformCPU(std::vector<glm::vec3>& vertexPositions, const glm::mat4x4& mvpMatrix)
{
    for (unsigned int i = 0 ; i < vertexPositions.size(); ++i) {
        glm::vec4 p = mvpMatrix * glm::vec4(vertexPositions[i], 1.0f);
        if (p.w ≠ 0.0f) {
            float inv = 1.0f / p.w;
                vertexPositions[i].x = p.x * inv;
                vertexPositions[i].y = p.y * inv;
                vertexPositions[i].z = p.z * inv;
        }
    }
}</pre>
```

• GPU: Transform in OpenGL 1.x (deprecated, DO NOT USE!)

```
void display(void)
   glClear (GL COLOR BUFFER BIT);
   glColor3f (1.0, 1.0, 1.0);
                     /* clear the matrix */
   glLoadIdentity ();
          /* viewing transformation */
   gluLookAt (0.0, 0.0, 5.0, 0.0, 0.0, 0.0, 0.0, 1.0, 0.0);
   glScalef (1.0, 2.0, 1.0); /* modeling transformation */
   glutWireCube (1.0);
  glFlush ();
void reshape (int w, int h)
   glViewport (0, 0, (GLsizei) w, (GLsizei) h);
  glMatrixMode (GL PROJECTION);
   glLoadIdentity ();
   glFrustum (-1.0, 1.0, -1.0, 1.0, 1.5, 20.0);
  glMatrixMode (GL MODELVIEW);
```

GPU (what we do with shader)

- In the CPU application, we
 - Load the scene data (from files)
 - Create vertex and index buffers
 - Provide material properties
 - Setup lights
 - Create and load shaders
 - Set up the rendering state (via OpenGL APIs)
 - Background color, polygon mode ... etc.
 - Set variable values to the GPU shaders
 - Transformation matrices, material data, light data ... etc.
 - Call "Draw" functions to render objects (via OpenGL APIs)
 - Vertex buffer format, primitive type, # of indices

set once unless they are changed at run time

- On the GPU, we
 - Execute the Vertex Shader for each vertex that belongs to a triangle
 - Vertex transformation
 - Vertex lighting (optional)
 - Prepare for interpolated vertex attributes (pass to fragment shader)

OpenGL performs rasterization by hardware

- Execute the Fragment Shader for each fragment generated by the rasterization for each triangle
 - Fragment shading (lighting, texturing ... etc.)

Modern Graphics Pipeline

- Modern graphics pipeline comprised more programmable (shader) stages, such as
 - Geometry shader in OpenGL 3.2
 - Tessellation control shader and tessellation evaluation shader in OpenGL 4.0
 - Compute shader in OpenGL 4.3
 - Mesh shader in OpenGL ?

 Hopefully, we could have time to introduce these shaders later in this semester

Supp: Load and Create an OpenGL Shader

```
GLuint AddShader(GLuint& progId, const std::string& sourceText, GLenum shaderType)
   GLuint shaderObj = glCreateShader(shaderType);
   if (shader0bj = 0) {
       std::cerr << "[ERROR] Failed to create stader with type " << shaderType << std::endl;
       exit(0);
                                                               Types:
                                                               GL_VERTEX_SHADER /
   const GLchar* p[1];
                                                               GL FRAGMENT SHADER
   p[0] = sourceText.c_str();
                                                               GL GEOMETRY SHADER
   GLint lengths[1];
   lengths[0] = (GLint)(sourceText.length());
                                                               GL_TESS_CONTROL_SHADER,
   glShaderSource(shaderObj, 1, p, lengths);
                                                               GL_TESS_EVALUATION_SHADER,
   qlCompileShader(shaderObj);
                                                               GL COMPUTE SHADER
   GLint success;
   qlGetShaderiv(shaderObj, GL_COMPILE_STATUS, &success);
   if (!success) {
       GLchar infoLog[MAX_BUFFER_SIZE];
       glGetShaderInfoLog(shaderObj, MAX_BUFFER_SIZE, NULL, infoLog);
       std::cerr << "[ERROR] Failed to compile shader with type: " << shaderType << ". Info: " << infoLog << std::endl;
       exit(1);
   glAttachShader(progId, shaderObj);
   return shaderObj;
```
